Human Mortality Forecasting for Developing Countries/Regions

Our Work

LSTM-based
Time-varying
LC Model

Mortality Data

Empirical
Results

- Many developing countries/regions have experienced a rapid mortality decline over the past few decades.
- Their recent mortality development trends are **NOT** necessarily driven by the same factors as their long-term behaviours.
- We propose a **time-varying mortality forecasting model** based on the **life expectancy** and **lifespan disparity** gap between these developing countries and a selected benchmark group (developed countries).
- We use a deep neural network model with an LSTM architecture to project the life expectancy and lifespan disparity difference, which further controls the rotation of the time-varying Lee-Carter (LC) model for three developing countries.

Time-Varying LC model

Our Work

LSTM-based
Time-varying
LC Model

Mortality Data

Empirical
Results

Let the logarithm of central death rate $m_{x,t}^j$ for a particular developing country j at age x and year t satisfies

$$\begin{aligned}\ln m_{x,t}^j &= a_x^j + b_{x,t}^j k_t^j + \varepsilon_{x,t}, \\ k_t^j &= d_t^j + k_{t-1}^j + \epsilon_t,\end{aligned}\tag{1}$$

The **main differences** between (1) and the classical LC method:

- the time-varying $b_{x,t}^j$ that measures a time-dependent age effect on mortality at different periods;
- the time-varying d_t^j describes a time-dependent drift in the random walk model used to project the period effect k_t^j .

Projection of Time-varying Factors

Our Work

LSTM-based
Time-varying
LC Model

Mortality Data

Empirical
Results

The age effect and drift terms of the period effect in the time-varying LC model are projected as

$$\begin{aligned} b_{x,t+1}^j &= (1 - \omega_t^b) \hat{b}_x^j + \omega_t^b \hat{B}_x \\ d_{t+1}^j &= (1 - \omega_t^d) \hat{d}^j + \omega_t^d \hat{d}_0, \end{aligned} \quad (2)$$

- \hat{b}_x^j and \hat{d}^j are the estimated LC parameters for country j ;
- \hat{B}_x and \hat{d}_0 are the estimated parameters of the Li-Lee model for the benchmark group.
- The key of such a time-varying LC model is the projection of the time-varying weights ω_t^b and ω_t^d .

Projection of Time-varying Factors

Our Work

LSTM-based
Time-varying
LC Model

Mortality Data

Empirical
Results

For simplicity, let $\omega_t^d = \omega_t^b = \omega_t$, for all $t \geq T$ (T is the maximum time for training in the data),

$$\omega_t = \left\{ \frac{1}{2} \left(1 + \sin \left[\frac{\pi}{2} \left(2 \max \left(\frac{g_T - g_t}{g_T}, 0 \right) - 1 \right) \right] \right) \right\}^p, \quad (3)$$

where g_t is the life expectancy and lifespan disparity gap at time t between the target country/region and the benchmark group.

- ω_t increases smoothly to 1 if the life expectancy/life disparity gap decreases in the projection phase.
- $p \in [0, 1]$ is a tuning parameter, we choose $p = 1$ such that ω_t has low rate of change close to 0 and 1.
- The life expectancy/life disparity gaps g_t are projected using a unified neural network model with LSTM architecture.

Mortality Data

- Benchmark group: Denmark, Finland, France, the Netherlands, Switzerland, Sweden, the U.K., the U.S., and Japan.
- The central death rates in the one-age and one-year blocks, ages equal to 0, 1, 2, 3, ... , 97, 98, 99, and years ranging from 1950 to 2019 (remove COVID-19 effects).
- The mortality data of developing countries/regions (e.g., Mainland China) is obtained from the United Nations population division.
- Note that a necessary condition for the application of our method is that the life expectancy or lifespan disparity of the target countries/regions converges to the ones of the benchmark group.
